

Tries retrieval
Priority queues and heaps

Map/Set ADT

- hash tables
- binary search tree
- tries

often used for strings

- "bat"
- "bats"

How do you connect each letter to children?

list

OR

```
class Node {
```

```
    val children: mutableMapOf
```

```
        <Char, Node>()
}
```

```
val s = "bat"
```

```
root = Node()
```

```
root.children[s[0]] = Node
```

key

value

BST: lookup, insert, etc

$O(n)$ really worst case

$O(\log n)$ balanced tree

$n = \#$ of items in tree

Tries: $O(k)$

$k = \text{length of the key}$

-really good for prefix searches

"Find all words starting w/ 'ba'"

ADT

Impl Strategies

Stack

Queues

{ arrays
linked lists

Map/set

tries, BSTs, hash tables

Priority Queue

heap

Priority Queue ADT

- insert(item)

- delete() \rightarrow returns item
with highest
Priority

\rightarrow typically return

* biggest, or smallest

PQ is defined for one or
the other

How do you implement a PQ?

use a list:

insert at end $O(1)$

delete: search for highest
priority $O(n)$

OR

insert into sorted position $O(n)$

delete: remove from end $O(1)$

Special kind of tree: heap

$O(\log n)$, guaranteed

for inserts and deletes

A ^{max} (min) heap is a binary tree

- where the value at every node is greater than its children (smaller)

- complete - every level is full except possibly last one,

which is full from the left

How to insert

#1 RULE OF HEAPS:

must preserve full levels
rule at all times.

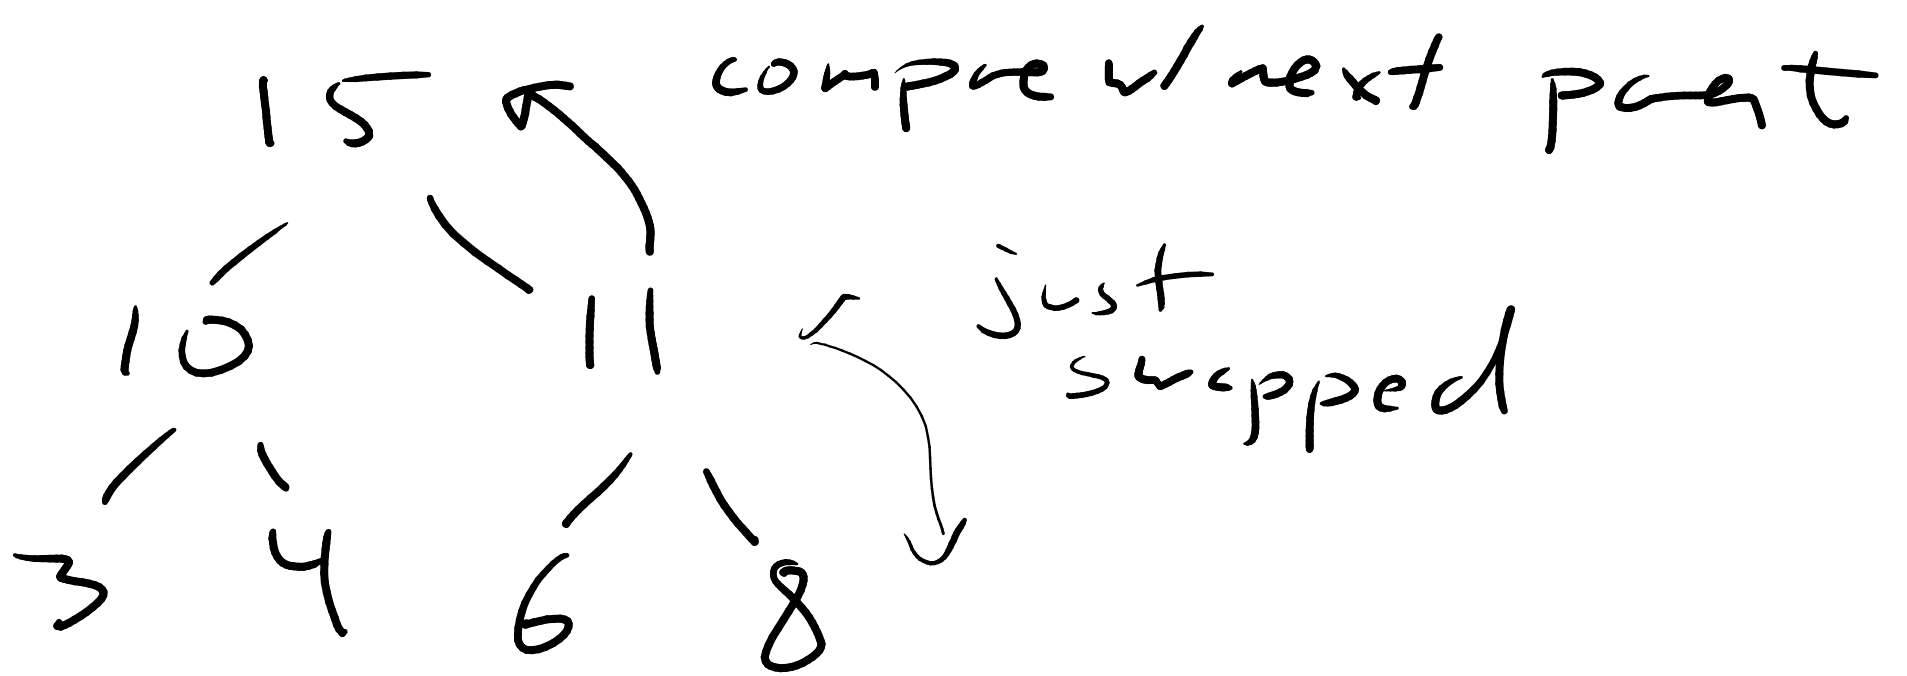

(Insert 11.)

Add new item at next legal
location on bottom row

Fix it (percolate up)

- compare w/ parent. If order
is wrong, swap

Repeat process until order
is correct, or pass the root
(Insert 20)

$O(\log n)$ work

Question
example

Peek: look at root $O(1)$

delete:

move last item to root

Fix ordering (percolate down)
Starting at root, check children
if at least one is greater,
swap it.
(if both are greater, swap up
larger one)

Repeat downward

How do you code/store this in memory?

Typically don't use node classes, pointers, etc.

Just use a list.

| 0 | 1 | 2 | 3 | 4 | 5 | 6 |
|----|----|----|---|---|---|---|
| 15 | 10 | 11 | 3 | 4 | 6 | 8 |

Where is root? location 0.

For any node at location i , its children are at

$2i+1$
and $2i+2$

Likewise, for a node j , its parent is $\frac{j-1}{2}$
(round down)

Inset 14

| | | | | | | | |
|----|----|----|---|---|---|---|----|
| 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| 15 | 10 | 11 | 3 | 4 | 6 | 8 | 14 |

| | | | | | | | |
|----|----|----|----|---|---|---|---|
| 15 | 10 | 11 | 14 | 4 | 6 | 8 | 3 |
|----|----|----|----|---|---|---|---|

| | | | | | | | |
|----|----|----|----|---|---|---|---|
| 15 | 14 | 11 | 10 | 4 | 6 | 8 | 3 |
|----|----|----|----|---|---|---|---|
